**Koji YOSHIDA, Hiroyuki EHARA  
Masahiro SERIZAWA and Kazunori OZAWA**

Applicant herewith submits to the United States Designated/Elected Office (DO/EO/US) the following items and other information:

1.  This is a **FIRST** submission of items concerning a filing under 35 U.S.C. 371.
2.  This is a **SECOND** or **SUBSEQUENT** submission of items concerning a filing under 35 U.S.C. 371.
3.  This is an express request to begin national examination procedures (35 U.S.C. 371(f)). The submission must include items (5), (6), (9) and (24) indicated below.
4.  The US has been elected by the expiration of 19 months from the priority date (Article 31).
5.  A copy of the International Application as filed (35 U.S.C. 371 (c) (2))
  - a.  is attached hereto (required only if not communicated by the International Bureau).
  - b.  has been communicated by the International Bureau.
  - c.  is not required, as the application was filed in the United States Receiving Office (RO/US).
6.  An English language translation of the International Application as filed (35 U.S.C. 371(c)(2)).
  - a.  is attached hereto.
  - b.  has been previously submitted under 35 U.S.C. 154(d)(4).
7.  Amendments to the claims of the International Application under PCT Article 19 (35 U.S.C. 371 (c)(3))
  - a.  are attached hereto (required only if not communicated by the International Bureau).
  - b.  have been communicated by the International Bureau.
  - c.  have not been made; however, the time limit for making such amendments has NOT expired.
  - d.  have not been made and will not be made.
8.  An English language translation of the amendments to the claims under PCT Article 19 (35 U.S.C. 371(c)(3)).
9.  An oath or declaration of the inventor(s) (35 U.S.C. 371 (c)(4)).
10.  An English language translation of the annexes to the International Preliminary Examination Report under PCT Article 36 (35 U.S.C. 371 (c)(5)).
11.  A copy of the International Preliminary Examination Report (PCT/IPEA/409).
12.  A copy of the International Search Report (PCT/ISA/210).

**Items 13 to 20 below concern document(s) or information included:**

13.  An Information Disclosure Statement under 37 CFR 1.97 and 1.98.
14.  An assignment document for recording. A separate cover sheet in compliance with 37 CFR 3.28 and 3.31 is included.
15.  A **FIRST** preliminary amendment.
16.  A **SECOND** or **SUBSEQUENT** preliminary amendment.
17.  A substitute specification.
18.  A change of power of attorney and/or address letter.
19.  A computer-readable form of the sequence listing in accordance with PCT Rule 13ter.2 and 35 U.S.C. 1.821 - 1.825.
20.  A second copy of the published international application under 35 U.S.C. 154(d)(4).
21.  A second copy of the English language translation of the international application under 35 U.S.C. 154(d)(4).
22.  Certificate of Mailing by Express Mail
23.  Other items or information:

DESCRIPTION

SPEECH DECODER AND CODE ERROR COMPENSATION METHOD

5 Technical Field

The present invention relates to a speech decoder and code error compensation method used in a mobile communication system and speech recorder, etc. that encode and then transmit speech signals.

10

Background Art

In the fields of digital mobile communications and speech storage, a speech coder is in use which compresses speech information and encodes compressed speech

15 information at low bit rates for effective utilization of radio waves and storage media. In this case, when an error occurs in the transmission path (or recording media), the decoding side detects the error and uses an error compensation method to suppress deterioration in the quality of decoded speech.

20 Examples of such a conventional art include an error compensation method are described in a CS-ACELP coding system of the ITU-T Recommendation G.729 ("Coding of speech at 8kbit/s using conjugate-structure algebraic-code-excited linear-prediction (CS-ACELP)").

25 FIG.1 is a block diagram showing a configuration of a speech decoder including error compensation

according to the CS-ACELP coding system. In FIG.1, suppose speech is decoded in 10 ms-frame units (decoding units) and whether any error is detected or not in the transmission path is notified to the speech decoder in 5 frame units.

First, the data received and coded in a frame in which no transmission path error has been detected is separated by data separation section 1 into parameters necessary for decoding. Then, using lag parameters 10 decoded by lag parameter decoding section 2, adaptive excitation codebook 3 generates adaptive excitation and fixed excitation codebook 4 generates fixed excitation. Furthermore, using a gain decoded by gain parameter decoding section 5, multiplier 6 performs multiplications 15 and adder 7 performs additions to generate an excitation. Furthermore, using LPC parameters decoded by LPC parameter decoding section 8, decoded speech is generated via LPC synthesis filter 9 and post filter 10.

On the other hand, with respect to the data received 20 and coded in a frame in which some transmission path error has been detected, an adaptive excitation is generated using the lag parameter of the previous frame in which no error has been detected as a lag parameter, and a fixed excitation is generated by giving fixed excitation 25 codebook 4 a random fixed excitation code and an excitation is generated using a value obtained by attenuating the adaptive excitation gain and fixed excitation gain of

the previous frame as a gain parameter, and LPC synthesis and post filter processing are carried out using the LPC parameter of the previous frame as an LPC parameter to obtain decoded speech.

5        In the event of a transmission path error, the above-described speech decoder can perform error compensation processing in this way.

However, since the above-described conventional speech decoder carries out same compensation processing  
10 irrespective of speech characteristics (voiced or unvoiced, etc.) in a frame in which an error is detected and carries out error compensation primarily using only past parameters, there are limits to improvement of deterioration in the quality of decoded speech during  
15 error compensation.

#### Disclosure of Invention

It is an object of the present invention to provide a speech decoder and error compensation method capable  
20 of achieving further improved quality for decoded speech in a frame in which an error is detected.

A main subject of the present invention is to allow a speech coding parameter to include mode information which expresses features of each short segment (frame)  
25 of speech and allow the speech decoder to adaptively calculate lag parameters and gain parameters used for speech decoding according to the mode information.

Furthermore, another main subject of the present invention is to allow the speech decoder to adaptively control the ratio of adaptive excitation gain and fixed excitation gain according to the mode information.

5 A further main subject of the present invention is to adaptively control adaptive excitation gain parameters and fixed excitation gain parameters used for speech decoding according to values of decoded gain parameters in a normal decoding unit in which no error is detected,  
10 immediately after a decoding unit whose coded data is detected to contain an error.

#### Brief Description of Drawings

FIG.1 is a block diagram showing a configuration  
15 of a conventional speech decoder;

FIG.2 is a block diagram showing a configuration of a radio communication system equipped with a speech coder and speech decoder according to an embodiment of the present invention;

20 FIG.3 is a block diagram showing a configuration of a speech decoder according to Embodiment 1 of the present invention;

FIG.4 is a block diagram showing an internal configuration of a lag parameter decoding section in the  
25 speech decoder according to Embodiment 1 of the present invention;

FIG.5 is a block diagram showing an internal

configuration of a gain parameter decoding section in the speech decoder according to Embodiment 1 of the present invention;

FIG.6 is a block diagram showing a configuration  
5 of a speech decoder according to Embodiment 2 of the present invention;

FIG.7 is a block diagram showing an internal configuration of a gain parameter decoding section in the speech decoder according to Embodiment 2 of the present  
10 invention;

FIG.8 is a block diagram showing a configuration of a speech decoder according to Embodiment 3 of the present invention; and

FIG.9 is a block diagram showing an internal configuration of a gain parameter decoding section in the speech decoder according to Embodiment 3 of the present  
15 invention.

#### Best Mode for Carrying out the Invention

20

With reference now to the attached drawings, embodiments of the present invention will be explained in detail below.

25 (Embodiment 1)

FIG.2 is a block diagram showing a configuration of a radio communication apparatus equipped with a speech

decoder according to Embodiment 1 of the present invention. Here, the "radio communication apparatus" refers to a base station apparatus or a communication terminal such as a mobile station, etc. in a digital radio communication system.

In this radio communication apparatus, speech is converted to an electric analog signal by speech input apparatus 101 such as a microphone on the transmitting side and output to A/D converter 102. The analog speech signal is converted to a digital speech signal by A/D converter 102 and output to speech coding section 103. Speech coding section 103 carries out speech coding processing on the digital speech signal and outputs the coded information to modulation/demodulation section 104. Modulation/demodulation section 104 digitally modulates the coded speech signal and sends the modulated signal to radio transmission section 105. Radio transmission section 105 applies predetermined radio transmission processing to the modulated signal. This signal is sent via antenna 106.

On the other hand, on the receiving side of the radio communication apparatus, a reception signal received by antenna 107 is subjected to predetermined radio reception processing by radio reception section 108 and sent to modulation/demodulation section 104.

Modulation/demodulation section 104 carries out demodulation processing on the reception signal and

outputs the demodulated signal to speech decoding section 109. Speech decoding section 109 carries out decoding processing on the demodulated signal to obtain digital decoded speech signal and outputs the digital decoded speech signal to D/A converter 110. D/A converter 110 converts the digital decoded speech signal output from speech decoding section 109 to an analog decoded speech signal and outputs to speech output apparatus 111 such as a speaker. Finally, speech output apparatus 111 converts the electrical analog decoded speech signal to decoded speech and outputs.

FIG.3 is a block diagram showing a configuration of a speech decoder according to Embodiment 1 of the present invention. The error compensation method in this speech decoder operates, when an error is detected on the speech decoding side from coded data obtained by the speech coding side coding an input speech signal, so as to suppress deterioration of the quality of decoded speech during speech decoding.

Here, speech is decoded in a certain short segment (called a "frame") on the order of 10 to 50 ms and the result of detection as to whether an error has occurred in reception data in the frame units or not is notified as an error detection flag. As the method of error detection, CRC (Cyclic Redundancy Check) or the like is normally used. Suppose error detection is performed outside this speech decoder beforehand. As data to be

subjected to error detection, all coded data for every frame may be targeted or only perceptually important coded data may be targeted.

Furthermore, the speech coding system to which the  
5 error compensation method of the present invention is applied is targeted for those speech coding parameters (transmission parameters) including at least mode information expressing frame-specific features of a speech signal, a lag parameter expressing information  
10 on the pitch period of the speech signal or adaptive excitation, and gain parameter expressing gain information of the excitation signal or speech signal.

First, a case where no error is detected in coded data of a current frame subjected to speech decoding will  
15 be explained first. In this case, no error compensation operation is performed, but normal speech decoding is performed. In FIG.3, data separation section 201 separates speech coding parameters from the coded data. Then, mode information decoding section 202, LPC  
20 parameter decoding section 203, lag parameter decoding section 204, and gain parameter decoding section 205 decode mode information, LPC parameter, lag parameter, and gain parameter, respectively.

Here, the mode information indicates a status of  
25 the speech signal in frame units and there are typically modes such as voiced, unvoiced and transient modes and the coding side carries out coding according to these

statuses. For example, in the case of CELP coding in MPE (Multi Pulse Excitation) mode of the standard ISO/IEC 14496-3 (MPEG-4 Audio) which is standardized by the ISO/IEC, the coding side groups mode information under 5 four modes such as unvoiced, transient, voiced (weak periodicity), and voiced (strong periodicity) according to the pitch predicted gain, and performs coding according to the mode.

The coding side then generates adaptive excitation 10 signals according to lag parameters using adaptive excitation codebook 206 and generates fixed excitation signals according to fixed excitation codes using fixed excitation codebook 207. A gain is multiplied by multiplier 208 on each excitation signal generated using 15 the decoded gain parameter and after two excitation signals are added up by adder 209, LPC synthesis filter 210 and post filter 211 generate and output a decoded 210 signal.

On the other hand, when an error is detected in the 20 coded data of the current frame, data separation section 201 separates the coded data into coding parameters first. Then, mode information decoding section 202 extracts the decoding mode information in the previous frame and uses this as the mode information of the current frame.

25 Furthermore, lag parameter decoding section 204 and gain parameter decoding section 205 adaptively calculate a lag parameter and gain parameter to be used for the

current frame according to the mode information using the lag parameter code, gain parameter code and mode information of the current frame obtained by data separation section 201. This calculation method will be  
5 described in detail later.

Furthermore, though any method can be used to decode an LPC parameter and fixed excitation parameter, it is also possible to use the LPC parameter of the previous frame as an LPC parameter and a fixed excitation signal  
10 generated by giving a random fixed excitation code as a fixed excitation parameter as in the case of the conventional art. It is also possible to use any noise signal generated by a random number generator as a fixed excitation signal or use the same fixed excitation code  
15 separated from the coded data of the current frame as a fixed excitation parameter.

As in the case where no error is detected, decoded speech is generated from each parameter obtained in this way through generation of an excitation signal, LPC  
20 synthesis and the post filter.

Next, the method of calculating a lag parameter to be used in the current frame when an error is detected will be explained using FIG.4. FIG.4 is a block diagram showing an internal configuration of lag parameter  
25 decoding section 204 in the speech decoder shown in FIG.3.

In FIG.4, the lag code of the current frame is decoded by lag decoding section 301 first. Then, frame internal

lag variation detection section 302 and inter-frame lag variation detection section 303 measure decoding lag parameter variations in a frame and between frames.

Lag parameters corresponding to one frame consist  
5 of a plurality of lag parameters corresponding to a plurality of subframes in the one frame and a lag variation in the frame is detected by detecting whether there is any difference exceeding a certain threshold among the plurality of lag parameters. On the other hand, a lag  
10 variation between frames is detected by comparing a plurality of lag parameters in a frame with the lag parameter of the previous frame (last subframe) and detecting whether there is any difference exceeding a certain threshold. Then, lag parameter determining  
15 section 304 determines a lag parameter to be used definitively in the current frame.

Then, the method of determining this lag parameter will be explained.

First, if the mode information shows "voiced", the  
20 lag parameter used in the previous frame is unconditionally used as the value of the current frame. Then, if the mode information shows "unvoiced" or "transient", the parameter decoded from the coded data of the current frame is used on condition that constraints  
25 will be put on lag variations in a frame or between frames.

More specifically, as shown in an example under expression (1), if all variations of frame internal

decoding lag parameter  $L(is)$  remain within a threshold, all those parameters are used as current frame lag parameter  $L'(is)$ .

On the other hand, when the frame internal lag varies beyond the threshold, inter-frame lag variations are measured. According to the detection result of these inter-frame lag variations, lag parameter  $L_{prev}$  of the previous frame (or previous subframe) is used as a lag parameter of a subframe with a greater variation from the previous frame (or previous subframe) (difference exceeding the threshold), while lag parameters of a subframe with small variations are used as they are.

if  $|L(j+1)-L(j)| < Tha$  for all  $j=1 \sim NS-2$ ,

$L'(is) = L(is)$  ( $is=0 \sim NS-1$ )

15 Else Expression(1)

$L'(is) = L(is)$ , if  $|L(is)-L_{prev}| < Thb$

$L_{prev}$  otherwise

where,  $L(is)$  denotes a decoding lag parameter;

$L'(is)$ , a lag parameter used in the current frame;  $NS$ ,

20 the number of subframes;  $L_{prev}$ , a lag parameter of the previous frame(or previous subframe);  $Tha$  and  $Thb$ ; thresholds.

It is also possible to decide a lag parameter to be used for the current frame from information of only frame internal variations or information of only inter-frame variations using only frame internal lag variation detection section 302 or inter-frame lag

variation detection section 303, respectively. It is also possible to apply the above-described processing only to the case where the mode information indicates "transient" and use the same lag parameter decoded from  
5 the coded data of the current frame in the case of "unvoiced".

The above explanation applies to the case where lag variation detection is performed on a lag parameter decoded from a lag code, but it is also possible to directly  
10 perform lag variation detection on a lag code value. A transient frame is a frame in which a lag parameter plays an important role as an onset of speech. Thus, in the above-described transient frame, it is possible to positively use decoding lag parameters obtained from the  
15 coded data of the current frame conditionally in such a way as to avoid deterioration due to coding errors. As a result, compared to the method using previous frame lag parameters unconditionally as in the case of the conventional art, it is possible to improve the quality  
20 of decoded speech.

Then, the method of calculating gain parameters to be used in the current frame when an error is detected will be explained using FIG.5. FIG.5 is a block diagram showing an internal configuration of gain parameter  
25 decoding section 205 in the speech decoder shown in FIG.3. In FIG.5, gain decoding section 401 decodes a gain parameter from the current parameter code of the current

frame.

In that case, when the gain decoding method varies depending on the mode information (e.g., the table used for decoding varies), decoding is performed according  
5 to the gain decoding method. As the mode information used in that case, the mode information decoded from the coded data of the current frame is used. However, as the method of expressing a gain parameter (coding method), if the  
10 method of expressing a gain value by combining a parameter that expresses power information of a frame (or subframe) and a parameter that expresses a correlation therewith (e.g., CELP coding in MPE mode of MPEG-4 Audio) is used, the value of the previous frame (or attenuated value of  
15 the previous frame) is used as the power information parameter.

Then, changeover section 402 changes processing according to the error detection flag and mode information. For frames in which no error is detected, a decoding gain parameter is output as is. On the other hand, for frames  
20 in which an error is detected, processing is changed according to the mode information.

First, when the mode information indicates "voiced", voiced frame gain compensation section 404 calculates a gain parameter to be used in the current frame. Any  
25 method may be used, but the gain parameter (adaptive excitation gain and fixed excitation gain) of the previous frame stored in gain buffer 403 attenuated by a certain

value can also be used as in the case of the conventional example.

Then, in the case where the mode information indicates "transient" or "unvoiced", unvoiced/transient frame gain control section 405 performs gain value control using the gain parameter decoded by gain decoding section 401. More specifically, using the gain parameter of the previous frame obtained from gain buffer 403 as a reference, an upper limit and lower limit (or either one) from that reference value are provided and a decoding gain parameter limited by the upper limit (and lower limit) is used as the gain parameter of the current frame. Expression (2) below shows an example of the limitation method when the upper limit is set for the adaptive excitation gain and fixed excitation gain.

If  $G_a > Th_a$

$Ge \leftarrow Th_a/G_a$

$G_a \leftarrow Th_a$

If  $Ge > Th_e * Ge_{prev}$

Expression (2)

$20 \quad G_a \leftarrow (Th_e * Ge_{prev}) / Ge$

$Ge \leftarrow Th_e * Ge_{prev}$

where,

$G_a$ : Adaptive excitation gain parameter

$Ge$ : Fixed excitation gain parameter

$25 \quad Ge_{prev}$ : Fixed excitation gain parameter of previous subframe

$Th_a, Th_e$ : Thresholds

As shown above, in a frame in which an error has been detected, in combination with the above-described lag parameter decoding section, the gain parameter code of the current frame that can contain some code errors 5 is positively used conditionally in such a way as to avoid deterioration due to coding errors. This can improve the quality of decoded speech compared to the method unconditionally using the gain parameter of the previous frame as in the case of the conventional art.

10 As described above, during speech decoding in a frame whose coded data is detected to contain an error, the lag parameter decoding section and gain parameter decoding section adaptively calculate a lag parameter and gain parameter to be used for speech decoding according 15 to the decoded mode information, and it is thereby possible to provide an error compensation method to achieve decoded speech of further improved quality.

More specifically, as a lag parameter to be used for speech decoding in the frame whose coded data is 20 detected to contain an error, when the mode information of the current frame in the above-described lag parameter determining section indicates "transient", or "transient" or "unvoiced" and at the same time there are few variations in the decoding lag parameter in a frame 25 or between frames, the decoding lag parameter decoded from the coded data of the current frame is used as the lag parameter of the current frame, and the past lag

parameter is used as the current lag parameter under other conditions, and it is thereby possible to provide an error compensation method capable of improving the quality of decoded speech when the error-detected frame corresponds 5 to an onset of the speech.

Furthermore, when an error is detected in the coded data of the current frame and at the same time the mode information indicates "transient" or "unvoiced", the above-described unvoiced/transient frame gain control 10 section controls the gain to be output with an upper limit to an increase and/or a lower limit to a decrease from the past gain parameter specified with respect to the gain parameter decoded from the coded data of the current frame, and can thereby suppress the gain parameter decoded 15 from the coded data that may possibly contain errors from taking an abnormal value due to the errors and provide an error compensation method capable of achieving further improved quality for decoded speech.

The error compensation method using the speech 20 decoder shown in FIG.3 above is targeted for a speech coding system including mode information that expresses features for every short segment of a speech signal as a coding parameter, while this error compensation method is also applicable to a speech coding system which does 25 not include speech mode information in its coding parameters. In that case, the decoding side can be provided with a mode calculation section to calculate

mode information to express features for every short segment of a speech signal from decoding parameters or decoding signals.

Moreover, the description of the speech decoder  
5 shown in FIG.3 above refers to a so-called CELP (Code Excited Linear prediction) type in which an excitation is expressed as a sum of an adaptive excitation and fixed excitation and decoded speech is generated through an  
10 LPC synthesis, while the error compensation method of the present invention is widely applicable to any speech coding system that uses pitch period information, gain information of an excitation or speech signal as coding parameters.

15 (Embodiment 2)

FIG.6 is a block diagram showing a configuration of a speech decoder according to Embodiment 2 of the present invention. As in the case of Embodiment 1, the error compensating method of the speech decoder of this  
20 embodiment operates, when the decoding side detects an error in coded data obtained by the speech coding side coding an input speech signal, in such a way as to suppress deterioration of the quality of the decoded speech during speech decoding by the speech decoder.

25 Here, speech decoding is performed in units of a predetermined short segment (called a "frame") on the order of 10 to 50 ms, and it is detected in frame units

whether an error has occurred in the reception data or not and the detection result is notified as a detection flag.

Suppose error detection is carried out outside this speech decoder beforehand. As data to be subjected to error detection, all coded data for every frame may be targeted or only perceptually important coded data may be targeted. Furthermore, the speech coding system to which the error compensation method of the present invention is applied is targeted for those speech coding parameters (transmission parameters) including at least mode information expressing frame-specific features of a speech signal, gain parameter expressing gain information of an adaptive excitation signal and fixed excitation signal.

The case where no error is detected in the coded data of the frame (current frame) to be subjected to speech decoding is the same as Embodiment 1 above and explanations thereof will be omitted.

When an error is detected in the coded data of the current frame, data separation section 501 separates the coded data into coding parameters first. Then, mode information decoding section 502 outputs the decoding mode information in the previous frame and uses this as the mode information of the current frame. This mode information is sent to gain parameter decoding section 505.

Furthermore, lag parameter decoding section 504 decodes lag parameters to be used for the current frame. Any method can be used to decode parameters, but as in the case of the conventional art, it is also possible 5 to use the lag parameter of the previous frame in which no error has been detected. Then, gain parameter decoding section 505 calculates a gain parameter using mode information using a method which will be described later.

Furthermore, any method can be used to decode LPC 10 parameters and fixed excitation parameters, but as in the case of the conventional art, it is also possible to use the LPC parameter of the previous frame as an LPC parameter and a fixed excitation signal generated by giving a random fixed excitation code as a fixed excitation 15 parameter. It is also possible to use any noise signal generated by a random number generator as a fixed excitation signal. Furthermore, it is also possible to perform decoding using the same fixed excitation code obtained by separating it from the coded data of the current 20 frame as a fixed excitation parameter. As in the case where no error is detected, decoded speech is generated from each parameter obtained in this way through generation of an excitation signal, LPC synthesis and the post filter.

25 Next, the method of calculating gain parameters to be used in the current frame when an error is detected will be explained using FIG.7. FIG.7 is a block diagram

showing an internal configuration of gain parameter decoding section 505 in the speech decoder shown in FIG. 6.

In FIG. 7, gain decoding section 601 decodes a gain parameter from the current parameter code of the current frame first. In that case, when the gain decoding method varies depending on the mode information (e.g., the table used for decoding varies, etc.), decoding is performed according to the gain decoding method. Then, changeover section 602 changes processing according to the error detection flag. For frames in which no error is detected, a decoded gain parameter is output as is.

On the other hand, for frames in which an error has been detected, adaptive excitation/fixed excitation gain ratio control section 604 carries out control of the adaptive excitation/fixed excitation gain ratio over the gain parameter (adaptive excitation gain and fixed excitation gain) of the previous frame stored in gain buffer 603 according to the mode information and outputs the gain parameter. More specifically, control is performed so as to increase the ratio of the adaptive excitation gain when the mode information of the current frame shows "voiced" and decrease the ratio of the adaptive excitation gain when the mode information of the current frame shows "transient" or "unvoiced".

However, the ratio is controlled so that the power of the excitation input to the LPC synthesis filter which adds up the adaptive excitation and fixed excitation is

equivalent to the power before the ratio control. In the case where error detection frames appear consecutively (also including one-time appearance), it is desirable to perform such control that attenuates the power of the  
5 excitation together.

It is also possible, instead of providing gain buffer 603, to provide a gain code buffer for storing past gain codes, for gain decoding section 601 to decode the gain using the gain code of the previous frame for a frame  
10 in which an error is detected and perform adaptive excitation/fixed excitation gain ratio control over the decoded gain.

Thus, in the case where the current frame subjected to error compensation is "voiced", by making the adaptive  
15 excitation component predominant, thereby making the voiced mode stationary, while making the fixed excitation component predominant in the unvoiced/transmit mode, it is possible to suppress deterioration by an inappropriate periodic component by the adaptive excitation and thereby  
20 improve the perceptual quality.

As described above, during speech decoding in a frame whose decoded data is detected to contain an error, the adaptive excitation/fixed excitation gain ratio control section performs adaptive excitation/fixed excitation  
25 gain ratio control over the gain parameter (adaptive excitation gain and fixed excitation gain) of the previous frame according to the mode information, and can thereby

provide an error compensation method that attains further improved quality for decoded speech.

The speech decoder shown in FIG.6 above is described as being targeted for a speech coding system including  
5 the mode information expressing features of every short segment of a speech signal as a coding parameter, but the error compensation method of the present invention is also applicable to a speech coding system whose coding parameter does not contain the mode information of speech.  
10 In that case, it is possible to include a mode calculation section for calculating mode information expressing features of every short segment of a speech signal from the decoding parameter or decoding signal on the decoding side.

15

(Embodiment 3)

FIG.8 is a block diagram showing a configuration of a speech decoder according to Embodiment 3 of the present invention. As in the case of Embodiments 1 and 2, the  
20 error compensating method of the speech decoder of this embodiment operates, when the decoding side detects an error in coded data obtained by the speech coding side coding an input speech signal, in such a way as to suppress deterioration of the quality of the decoded speech during  
25 speech decoding by the speech decoder.

Here, speech decoding is performed in units of a predetermined short segment (called a "frame") on the

order of 10 to 50 ms, and it is detected in frame units whether an error has occurred in the reception data or not and the detection result is notified as a detection flag. Suppose error detection is carried out outside this speech decoder beforehand. As data to be subjected to error detection, all coded data for every frame may be targeted or only perceptually important coded data may be targeted.

Furthermore, the speech coding system to which the error compensation method of the present invention is applied is targeted for those speech coding parameters (transmission parameters) including at least a gain parameter expressing gain information of an adaptive excitation code signal and fixed excitation code signal.

In a frame in which no transmission path error is detected, data separation section 701 separates the coded data into parameters necessary for decoding first. Then, using the lag parameter decoded by lag parameter decoding section 702, adaptive excitation codebook 703 generates an adaptive excitation and fixed excitation codebook 704 generates a fixed excitation.

Furthermore, using the gain decoded by gain parameter decoding section 705 using the method which will be described later, an excitation is generated through a multiplication and addition of gains by multiplier 706 and adder 707. Then, decoded speech is generated via LPC synthesis filter 709 and post filter

710 using these excitation and the LPC parameter decoded by LPC parameter decoding section 708.

On the other hand, for frames in which some transmission path error is detected, each decoding 5 parameter is generated, and then decoded speech is generated in the same way as for frames in which no error is detected. Any method can be used to decode parameters except gain parameters, but as in the case of the conventional art, it is also possible to use the parameter 10 of the previous frame as the LPC parameter and lag parameter.

Furthermore, it is also possible to perform decoding using a fixed excitation signal generated by giving a random fixed excitation code as a fixed excitation 15 parameter, using an arbitrary noise signal generated by a random number generator as a fixed excitation signal, or using the same fixed excitation code separated from the coded data of the current frame as a fixed excitation parameter, etc.

Next, the method of decoding gain parameters by the gain parameter decoding section will be explained using FIG.9. FIG.9 is a block diagram showing an internal configuration of gain parameter decoding section 705 in the speech decoder shown in FIG.8. In FIG.9, the gain 25 parameter is decoded by gain decoding section 801 from the current parameter code of the current frame first. Furthermore, error status monitoring section 802 decides

the status of error detection according to whether an error is detected or not. This status corresponds to the current frame in any one of the following cases:

      Status 1) Error-detected frame

5       Status 2) Consecutive (including the case of one time continuation) normal (no error is detected) frames immediately after an error-detected frame

      Status 3) Other frames in which no error is detected

10      Then, changeover section 803 changes processing according to above-described status. In the case of status 3), a gain parameter decoded by gain decoding section 801 is output as is.

      Then, in the case of status 1), a gain parameter in the error-detected frame is calculated. Any method can be used to calculate the gain parameter and it is also possible to use a value obtained by attenuating the adaptive excitation gain and fixed excitation gain of the previous frame as in the case of the conventional art. It is also possible to carry out decoding using the gain code of the previous frame and use it as the gain parameter of the current frame. It is further possible, as shown in Embodiment 1 or 2, to use lag gain parameter control according to the mode and gain parameter ratio control according to the mode.

25      Then, in status 2), adaptive excitation/fixed excitation gain control section 806 carries out the following processing on a normal frame after the error

detection. First, of the gain parameters decoded by gain decoding section 801, the value of the adaptive excitation gain (coefficient value multiplied on the adaptive excitation) is subjected to control with an upper value  
 5 specified. More specifically, it is possible to specify a fixed value (e.g., 1.0) as the upper limit, decide an upper limit that is proportional to the decoded adaptive excitation gain value or combine them. Furthermore,  
 10 together with the above-described adaptive excitation gain upper value control, the fixed excitation gain is also controlled simultaneously in such a way as to correctly maintain the ratio of the adaptive excitation gain to the fixed excitation gain. An example of a specific implementation method is shown in expression  
 15 (3) below.

For a certain number of first subframes in status  
 2),

```

if Ga > 1.0

    Ge ← (1.0/Ga)*Ge

20      Ga ← 1.0
  
```

For subframes exceeding the above case in status  
 2)

Expression (3)

```

if Ga > 1.0

    Ge ← {{{(Ga+1.0)/2}/Ga}*Ge

25      Ga ← (Ga+1.0)/2
  
```

where,

Ga: Adaptive excitation gain

Ge: Fixed excitation gain

When a method of expressing a gain value using a combination of a parameter expressing frame (or subframe) power information and a parameter expressing a correlation therewith (e.g., CELP coding in MPE mode of MPEG-4 Audio) is adopted as the method of expressing a gain parameter (coding method), an adaptive excitation gain is decoded depending on the decoded excitation of the previous frame, and therefore in the case of a normal frame after error detection, the adaptive excitation gain is different from the original value because of the error compensation processing of the previous frame and its quality may sometimes deteriorate due to an abnormal amplitude expansion of the decoded speech. However, quality deterioration can be suppressed by limitation of gain with the upper limit in this embodiment.

Furthermore, by controlling the ratio of adaptive excitation gain to fixed excitation gain so that this ratio becomes the value with the original decoding gain without errors, the excitation signal in the normal frame after error detection becomes more similar to an excitation in the case of no error, thus making it possible to improve the quality of decoded speech.

The coding error compensation methods in above-described Embodiments 1 to 3 can also be configured by software. For example, it is possible to store the program of the above-described error compensation method

in a ROM and construct a system so as to operate under instructions from the CPU according to the program. Or it is also possible to store the program, adaptive excitation codebook, and fixed excitation codebook in 5 a computer-readable storage medium and store the program, adaptive excitation codebook, and fixed excitation codebook of this storage medium in a RAM of the computer and operate the system according to the program. These cases also show the same actions and effects as in 10 above-described Embodiments 1 to 3.

The speech decoder of the present invention adopts a configuration comprising receiving means for receiving data containing coded transmission parameters including 15 mode information, lag parameter and gain parameter, a decoding section for decoding the above-described mode information, lag parameter and gain parameter, and a determining section for using mode information corresponding to a decoding unit earlier than the decoding 20 unit corresponding to the above-described data in which an error is detected and adaptively determining a lag parameter and gain parameter to be used for the above-described decoding unit.

According to this configuration, when speech is 25 decoded in the decoding unit whose coded data is detected to contain an error, a lag parameter and gain parameter to be used for speech decoding are adaptively calculated

according to the decoded mode information, and it is thereby possible to provide further improved quality for decoded speech.

The speech decoder of the present invention in the above-described configuration also adopts a configuration wherein the determining section comprises a detection section for detecting variations within a lag parameter decoding unit and/or between lag parameter decoding units and determines a lag parameter to be used in the above-described decoding unit according to the detection result of the above-described detection section and the above-described mode information.

According to this configuration, when speech is decoded in the decoding unit whose coded data is detected to contain an error, a lag parameter to be used for speech decoding is adaptively calculated according to the decoded mode information and the results of detection of variations within a decoding unit and/or between decoding units, and it is thereby possible to provide further improved quality for decoded speech.

The speech decoder of the present invention in the above-described configuration also adopts a configuration wherein the above-described lag parameter corresponding to the decoding unit is used when the mode indicated by the mode information is a transient mode or unvoiced mode and when the detection section detects no variations exceeding a predetermined amount within

a lag parameter decoding unit and/or between lag parameter decoding units, and the lag parameter corresponding to a past decoding unit is used in other cases.

According to this configuration, it is possible to  
5 improve the quality of decoded speech especially when  
the error detection decoding unit corresponds to an onset  
of speech.

The speech decoder of the present invention in the  
above-described configuration also adopts a  
10 configuration wherein when the mode indicated by the mode  
information is a transient mode or unvoiced mode, the  
determining section comprises a restriction control  
section for putting restrictions on the range of gain  
parameters according to gain parameters corresponding  
15 to a past decoding unit and determines a gain parameter  
subjected to the range restrictions as the gain parameter.

According to this configuration, when an error is  
detected in coded data of the current decoding unit and  
at the same time the mode information indicates a transient  
20 or unvoiced mode, the output gain is controlled by  
specifying an upper limit to an increase and/or lower  
limit to a decrease from the past gain parameter, thereby  
making it possible to suppress the gain parameter decoded  
from the coded data that can contain an error from taking  
25 an abnormal value due to the error and provide further  
improved quality for decoded speech.

The speech decoder of the present invention adopts

a configuration comprising a reception section for receiving data containing coded transmission parameters including mode information, lag parameter, fixed excitation parameter and gain parameter made up of an  
5 adaptive excitation gain and fixed excitation gain, a decoding section for decoding the above-described mode information, lag parameter, fixed excitation parameter and gain parameter, and a ratio control section for controlling the ratio of the adaptive excitation gain  
10 to the fixed excitation gain using mode information corresponding to a decoding unit earlier than the decoding unit whose data is detected to contain an error.

The speech decoder of the present invention in the above-described configuration also adopts a  
15 configuration wherein the above-described ratio control section controls the gain ratio in such a way as to increase the ratio of the adaptive excitation gain when the mode information is a voiced mode and decrease the ratio of the adaptive excitation gain when the mode information  
20 is a transient mode or unvoiced mode.

According to these configurations, when a gain parameter is decoded in the decoding unit whose coded data is detected to contain an error, the ratio of the adaptive excitation gain to the fixed excitation gain  
25 is adaptively controlled according to the mode information, making it possible to further perceptually improve the quality of decoded speech in error detection

decoding units.

The speech decoder of the present invention adopts a configuration comprising a reception section for receiving data containing coded transmission parameters 5 including a lag parameter, fixed excitation parameter and gain parameter made up of an adaptive excitation gain and fixed excitation gain, a decoding section for decoding the above-described lag parameter, fixed excitation parameter and gain parameter, and a specifying section 10 for specifying an upper limit of the gain parameter in a normal decoding unit immediately after the decoding unit in which an error is detected.

According to this configuration, in a normal decoding unit with no errors detected immediately after 15 the decoding unit whose coded data is detected to contain an error, control is performed so as to specify the upper limit of the decoded adaptive excitation gain parameter, thereby making it possible to suppress deterioration of the quality of decoded speech due to an abnormal amplitude 20 expansion of the decoded speech signal in the normal decoding unit immediately after the error detection.

The speech decoder of the present invention in the above-described configuration also adopts a configuration wherein the above-described specifying 25 section controls the fixed excitation gain so as to maintain a predetermined ratio with respect to the adaptive excitation gain within a range whose upper limit

is specified.

According to this configuration, since the ratio between the adaptive excitation gain and fixed excitation gain is controlled to take a value with an original decoding 5 gain without errors, the excitation signal in the normal decoding unit immediately after the error detection becomes more similar to the case with no errors, and it is thereby possible to improve the quality of decoded speech.

10       The speech decoder of the present invention adopts a configuration comprising a reception section for receiving data containing coded transmission parameters including a lag parameter and gain parameter, a decoding section for decoding the above-described lag parameter  
15       and gain parameter, a mode calculation section for calculating mode information from a decoding parameter or decoding signal obtained by decoding the above-described data, and a determining section for using mode information corresponding to a decoding unit earlier  
20       than the decoding unit corresponding to the above-described data in which an error is detected and adaptively determining a lag parameter and gain parameter to be used for the above-described decoding unit.

According to this configuration, it is possible to 25 adaptively calculate a lag parameter and gain parameter to be used for speech decoding even for the speech coding system whose coding parameter includes no speech mode

information according to the mode information calculated on the decoding side, and thereby provide further improved quality for decoded speech.

The speech decoder of the present invention adopts  
5 a configuration comprising a reception section for receiving data containing coded transmission parameters including a lag parameter, fixed excitation parameter and gain parameter made up of an adaptive excitation gain and fixed excitation gain, a decoding section for decoding  
10 the above-described lag parameter, fixed excitation parameter and gain parameter, a mode calculation section for calculating mode information from a decoding parameter or decoding signal obtained by decoding the above-described data, and a ratio control section for  
15 controlling the ratio of the adaptive excitation gain to the fixed excitation gain using mode information corresponding to a decoding unit earlier than the decoding unit whose data is detected to contain an error.

According to this configuration, when a gain  
20 parameter is decoded in the decoding unit whose coded data is detected to contain an error, the ratio of the adaptive excitation gain to the fixed excitation gain is adaptively controlled according to the mode information calculated on the decoding side even for the  
25 speech coding system whose coding parameter includes no speech mode information, making it possible to further perceptually improve the quality of decoded speech in

error detection decoding units.

The code error compensation method of the present invention comprises a step of decoding mode information, lag parameter and gain parameter in data containing coded transmission parameters including the mode information, lag parameter and gain parameter, and a determining step of using mode information corresponding to a decoding unit earlier than the decoding unit corresponding to the above-described data in which an error is detected and adaptively determining a lag parameter and gain parameter to be used for the above-described decoding unit.

According to this method, when speech is decoded in the decoding unit whose coded data is detected to contain an error, a lag parameter and gain parameter to be used for speech decoding are adaptively calculated according to the decoded mode information, and it is thereby possible to provide further improved quality for decoded speech.

The code error compensation method of the present invention in the above-described method also comprises a step of detecting variations within a lag parameter decoding unit and/or between lag parameter decoding units and determines a lag parameter to be used in the above-described decoding unit according to the detection result and the mode information.

According to this method, when speech is decoded in the decoding unit whose coded data is detected to contain an error, a lag parameter to be used for speech decoding

is adaptively calculated according to the decoded mode information and the results of detection of variations within a decoding unit and/or between decoding units, and it is thereby possible to provide further improved  
5 quality for decoded speech.

The code error compensation method of the present invention in the above-described method also uses the above-described lag parameter with respect to the decoding unit when the mode indicated by the mode  
10 information is a transient mode or unvoiced mode and when no variations exceeding a predetermined amount within a lag parameter decoding unit and/or between lag parameter decoding units are detected, and uses the lag parameter corresponding to a past decoding unit in other cases.

15 According to this method, it is possible to improve the quality of decoded speech especially when the error detection decoding unit corresponds to an onset of speech.

The code error compensation method of the present invention in the above-described method puts restrictions  
20 on the range of gain parameters according to gain parameters corresponding to a past decoding unit and determines a gain parameter subjected to the range restrictions as the gain parameter when the mode indicated by the mode information is a transient mode or unvoiced  
25 mode.

According to this method, when an error is detected in coded data of the current decoding unit and at the

same time the mode information indicates a transient or unvoiced mode, the output gain is controlled for the gain parameter decoded from the coded data of the current decoding unit by specifying an upper limit to an increase 5 and/or lower limit to a decrease from the past gain parameter, thereby making it possible to suppress the gain parameter decoded from the coded data that can contain an error from taking an abnormal value due to the error and provide further improved quality for decoded speech.

10       The code error compensation method of the present invention comprises a step of receiving data containing coded transmission parameters including mode information, lag parameter, fixed excitation parameter and gain parameter made up of an adaptive excitation gain and fixed 15 excitation gain, a step of decoding the above-described mode information, lag parameter, fixed excitation parameter and gain parameter, and a step of controlling the ratio of the adaptive excitation gain to the fixed excitation gain using mode information corresponding to 20 a decoding unit earlier than the decoding unit whose data is detected to contain an error.

25       The code error compensation method of the present invention in the above-described method controls the gain ratio in such a way as to increase the ratio of the adaptive excitation gain when the mode indicated by the mode information is a voiced mode and decrease the ratio of the adaptive excitation gain when the mode indicated by

the mode information is a transient mode or unvoiced mode.

According to these methods, when a gain parameter is decoded in the decoding unit whose coded data is detected to contain an error, the ratio of the adaptive excitation

5 gain to the fixed excitation gain is adaptively controlled according to the mode information, making it possible to further perceptually improve the quality of decoded speech in error detection decoding units according to the mode information.

10 The code error compensation method of the present invention comprises a step of receiving data containing coded transmission parameters including a lag parameter, fixed excitation parameter and gain parameter made up of an adaptive excitation gain and fixed excitation gain, 15 a step of decoding the above-described lag parameter, fixed excitation parameter and gain parameter, and a step of specifying an upper limit of the gain parameter in a normal decoding unit immediately after the decoding unit in which an error is detected.

20 According to this method, in a normal decoding unit immediately after the decoding unit whose coded data is detected to contain an error, control is performed so as to specify the upper limit of the decoded adaptive excitation gain parameter, thereby making it possible 25 to suppress deterioration of the quality of decoded speech due to an abnormal amplitude expansion of the decoded speech signal in the normal decoding unit immediately

after the error detection.

The code error compensation method of the present invention in the above-described method controls the fixed excitation gain so as to maintain a predetermined ratio with respect to the adaptive excitation gain within a range whose upper limit is specified.

According to this method, since the ratio between the adaptive excitation gain and fixed excitation gain is controlled so as to have a value with an original decoding gain without errors, the excitation signal in a normal decoding unit immediately after the error detection becomes more similar to the case with no errors, and it is thereby possible to improve the quality of decoded speech.

The code error compensation method of the present invention comprises a step of receiving data containing coded transmission parameters including a lag parameter and gain parameter, a step of decoding the above-described lag parameter and gain parameter, a step of calculating mode information from a decoding parameter or decoding signal obtained by decoding the above-described data, and a step of using the mode information corresponding to a decoding unit earlier than the decoding unit whose data is detected to contain an error and adaptively determining a lag parameter and gain parameter to be used for the above-described decoding unit.

According to this method, it is possible to

adaptively calculate a lag parameter and gain parameter to be used for speech decoding even for the speech coding system whose coding parameter includes no speech mode information according to the mode information calculated 5 on the decoding side, and thereby provide further improved quality for decoded speech.

The recording medium of the present invention is a computer-readable recording medium for storing a program and this program comprises a step of decoding 10 mode information, lag parameter data and gain parameter in data containing coded transmission parameters including the mode information, lag parameter and gain parameter, and a step of using the mode information corresponding to a decoding unit earlier than the decoding 15 unit whose data is detected to contain an error and adaptively determining a lag parameter and gain parameter to be used for the above-described decoding unit.

According to this medium, it is possible to adaptively calculate a lag parameter and gain parameter 20 to be used for speech decoding when speech decoding is performed in the decoding unit whose coded data is detected to contain an error according to the decoded mode information, and thereby provide further improved quality for decoded speech.

25 The recording medium of the present invention is a computer-readable recording medium for storing a program and this program comprises a step of decoding

mode information, lag parameter data and gain parameter in data containing coded transmission parameters including the mode information, lag parameter and gain parameter, and a step of using the mode information  
5 corresponding to a decoding unit earlier than the decoding unit whose data is detected to contain an error and controlling the ratio of the adaptive excitation gain to the fixed excitation gain in such a way as to increase the ratio of the adaptive excitation gain when the mode  
10 indicated by the above-described mode information is a voiced mode and decrease the ratio of the adaptive excitation gain when the mode indicated by the above-described mode information is a transient mode or unvoiced mode.

15 According to this medium, when a gain parameter is decoded in the decoding unit whose coded data is detected to contain an error, the ratio of the adaptive excitation gain to the fixed excitation gain is adaptively controlled according to the mode information, making it possible  
20 to further perceptually improve the quality of decoded speech in error detection decoding units.

The recording medium of the present invention is a computer-readable recording medium for storing a program and this program comprises a step of decoding  
25 a lag parameter and gain parameter in data containing coded transmission parameters including the lag parameter and gain parameter, and a step of specifying an upper

limit of the gain parameter in a normal decoding unit immediately after the decoding unit in which an error is detected and controlling the fixed excitation gain so as to maintain a predetermined ratio with respect to  
5 the adaptive excitation gain within the range whose upper limit is specified.

According to this medium, it possible to suppress deterioration of the quality of decoded speech due to an abnormal amplitude expansion of the decoded speech  
10 signal in the normal decoding unit immediately after the error detection.

As described above, according to the speech decoder and code error compensation method of the present invention, when speech is decoded in a frame whose coded  
15 data is detected to contain an error, the lag parameter decoding section and gain parameter decoding section adaptively calculate a lag parameter and gain parameter to be used for speech decoding according to the decoded mode information. This makes it possible to provide  
20 further improved quality for decoded speech.

Furthermore, according to the present invention, when a gain parameter is decoded in a frame whose coded data is detected to contain an error, the gain parameter decoding section adaptively controls the ratio of the  
25 adaptive excitation gain to the fixed excitation gain according to the mode information. More specifically, by controlling the gain ratio so that the ratio of the

adaptive excitation gain is increased when the current frame shows a voiced mode and decreased when the current frame shows a transient or unvoiced mode, it is possible to further perceptually improve the quality of decoded speech of an error detection frame.

Furthermore, according to the present invention, the gain parameter decoding section adaptively controls the adaptive excitation gain parameter and fixed excitation gain parameter to be used for speech decoding according to the value of the decoding gain parameter for a normal frame in which no error is detected immediately after the frame whose coded data is detected to contain an error. More specifically, the gain parameter decoding section controls in such a way as to specify the upper limit of the decoded adaptive excitation gain parameter. This makes it possible to suppress deterioration of the quality of decoded speech due to an abnormal amplitude expansion of the decoded speech signal in the normal frame unit immediately after the error detection. Furthermore, by controlling the ratio of the adaptive excitation gain to the fixed excitation gain so that it becomes the value with the original decoding gain without errors and thereby making the excitation signal in the normal frame after the error detection more similar to the case with no errors, it is possible to improve the quality of decoded speech.

entire content of which is expressly incorporated by  
reference herein.

5 Industrial Applicability

The present invention is applicable to a base station apparatus and communication terminal apparatus in a digital radio communication system. This makes it possible to carry out radio communications resistant to

10 transmission errors.

What is claimed is:

1. A speech decoder comprising:

receiving means for receiving data containing coded  
5 transmission parameters including mode information, a  
lag parameter, and a gain parameter;  
decoding means for decoding said mode information,  
said lag parameter, and said gain parameter; and  
determining means for using said mode information  
10 corresponding to a decoding unit decoded previous to a  
decoding unit including said data in which an error is  
detected and adaptively determining a lag parameter and  
a gain parameter to be used for said decoding unit.

15 2. The speech decoder according to claim 1, wherein the  
determining means comprises detecting means for detecting  
variations within a lag parameter decoding unit and/or  
between lag parameter decoding units, and determines a  
lag parameter to be used for said decoding unit according  
20 to the detection result of said detecting means and said  
mode information.

25 3. The speech decoder according to claim 2, wherein said  
lag parameter corresponding to the decoding unit is used  
when the mode indicated by mode information is transient  
mode or unvoiced mode and said detecting means detects  
no variations exceeding a predetermined amount within

a lag parameter decoding unit and/or between lag parameter decoding units and the lag parameter corresponding to a past decoding unit is used in other cases.

5 4. The speech decoder according to claim 1, wherein the determining means comprises a restriction controlling means for putting restrictions on the range of gain parameters according to gain parameters corresponding to a past decoding unit, when the mode indicated by mode  
10 information is transient mode or unvoiced mode, and determines a gain parameter subjected to the range restriction as the gain parameter.

5. A speech decoder comprising:

15 receiving means for receiving data containing coded transmission parameters including mode information, a lag parameter, a fixed excitation parameter, and a gain parameter made up of an adaptive excitation gain and a fixed excitation gain;

20 decoding means for decoding said mode information, a lag parameter, a fixed excitation parameter, and a gain parameter; and

ratio controlling means for controlling the ratio of said adaptive excitation gain to said fixed excitation  
25 gain using mode information corresponding to a decoding unit decoded previous to a decoding unit including said data in which an error is detected.

6. The speech decoder according to claim 5, wherein said ratio control means controls the gain ratio in such a way as to increase the ratio of the adaptive excitation gain when said mode information is a voiced mode and  
5 decrease the ratio of the adaptive excitation gain when said mode information is transient mode or unvoiced mode.

7. A speech decoder comprising:

receiving means for receiving data containing coded  
10 transmission parameters including a lag parameter, a fixed excitation parameter, and a gain parameter made up of an adaptive excitation gain and fixed excitation gain;

decoding means for decoding said lag parameter, said  
15 fixed excitation parameter, and said gain parameter; and specifying means for specifying an upper limit of the gain parameter in a normal decoding unit decoded immediately after decoding a decoding unit in which an error is detected.

20

8. The speech decoder according to claim 7, wherein said specifying means controls the fixed excitation gain so as to maintain a predetermined ratio with respect to the adaptive excitation gain within a range whose upper limit  
25 is specified.

9. A speech decoder comprising:

receiving means for receiving data containing coded transmission parameters including a lag parameter and a gain parameter;

decoding means for decoding said lag parameter and  
5 said gain parameter;

mode calculating means for calculating mode information from a decoding parameter or a decoding signal obtained by decoding said data; and

10 determining means for using the mode information corresponding to a decoding unit decoded previous to a decoding unit corresponding to said data in which an error is detected and adaptively determining a lag parameter and a gain parameter to be used for said decoding unit.

15 10. A speech decoder comprising:

receiving means for receiving data containing coded transmission parameters including a lag parameter, a fixed excitation parameter, and a gain parameter made up of an adaptive excitation gain and a fixed excitation  
20 gain;

decoding means for decoding said lag parameter, said fixed excitation parameter, and said gain parameter;

mode calculating means for calculating mode information from a decoding parameter or a decoding signal  
25 obtained by decoding said data; and

ratio controlling means for controlling the ratio of said adaptive excitation gain to said fixed excitation

gain using mode information corresponding to a decoding unit decoded previous to the decoding unit corresponding to said data in which an error is detected.

5 11. A code error compensation method comprising:

a decoding step of decoding mode information, a lag parameter, and a gain parameter in data containing coded transmission parameters including said mode information, said lag parameter, and said gain parameter; and

10 a determining step of using mode information corresponding to a decoding unit decoded previous to a decoding unit corresponding to said data in which an error is detected and adaptively determining a lag parameter and a gain parameter to be used for said decoding unit.

15

12. The code error compensation method according to claim 11, which further comprises a detecting step of detecting variations within a lag parameter decoding unit and/or between lag parameter decoding units, and determines a 20 lag parameter to be used for said decoding unit according to the detection result and said mode information.

25 13. The code error compensation method according to claim 12, which uses said lag parameter corresponding to the decoding unit when the mode indicated by the mode information is transient mode or unvoiced mode and when no variations exceeding a predetermined amount within

a lag parameter decoding unit and/or between lag parameter decoding units are detected and uses a lag parameter corresponding to a past decoding unit in other cases.

5 14. The code error compensation method according to claim  
11, wherein restrictions are put, when the mode indicated  
by mode information is transient mode or unvoiced mode,  
on the range of gain parameters according to gain  
parameters corresponding to a past decoding unit, and  
10 determines a gain parameter subjected to the range  
restrictions as the gain parameter.

15. A code error compensation method comprising:  
a receiving step of receiving data containing coded  
15 transmission parameters including mode information, a  
lag parameter, a fixed excitation parameter, and a gain  
parameter made up of an adaptive excitation gain and a  
fixed excitation gain;  
a decoding step of decoding said mode information,  
20 said lag parameter, said fixed excitation parameter, and  
said gain parameter; and  
a controlling step of controlling the ratio of said  
adaptive excitation gain to said fixed excitation gain  
using mode information corresponding to a decoding unit  
25 decoded previous to a decoding unit including said data  
in which an error is detected.

16. The code error compensation method according to claim  
15, which controls the gain ratio between the adaptive  
excitation gain and the fixed excitation gain in such  
a way as to increase the ratio of the adaptive excitation  
5 gain when the mode information is voiced mode and decrease  
the ratio of the adaptive excitation gain when the mode  
information is transient mode or unvoiced mode.

17. A code error compensation method comprising:

10        a receiving step of receiving data containing coded  
transmission parameters including a lag parameter, a  
fixed excitation parameter, and a gain parameter made  
up of an adaptive excitation gain and a fixed excitation  
gain;

15        a decoding step of decoding said lag parameter, said  
fixed excitation parameter, and said gain parameter; and  
            a specifying step of specifying an upper limit of  
the gain parameter in a normal decoding unit decoded  
immediately after decoding a decoding unit in which an  
20      error is detected.

18. The code error compensation method according to claim  
17, which controls the fixed excitation gain so as to  
maintain a predetermined ratio with respect to the  
25      adaptive excitation gain within a range whose upper limit  
is specified.

19. A code error compensation method comprising:  
a receiving step of receiving data containing coded  
transmission parameters including a lag parameter and  
a gain parameter;

5       a decoding step of decoding said lag parameter and  
said gain parameter;

          a calculating step of calculating mode information  
from a decoding signal obtained by decoding said data;  
and

10      a determining step of using mode information  
corresponding to a decoding unit decoded previous to a  
decoding unit corresponding to said data in which an error  
is detected and adaptively determining a lag parameter  
and a gain parameter to be used for said decoding unit.

15

20. A computer-readable recording medium for storing a  
program, said program comprising:

          a decoding step of decoding mode information, a lag  
parameter, and a gain parameter in data containing coded

20     transmission parameters including said mode information,  
said lag parameter, and said gain parameter; and

          a determining step of using mode information  
corresponding to a decoding unit decoded previous to a  
decoding unit corresponding to said data in which an error  
25    is detected and adaptively determining a lag parameter  
and a gain parameter to be used for said decoding unit.

21. A computer-readable recording medium for storing a program, said program comprising:

a decoding step of decoding mode information, a lag parameter, and a gain parameter in data containing coded

5 transmission parameters including said mode information, said lag parameter, and said gain parameter; and

a controlling step of using mode information corresponding to a decoding unit decoded previous to a decoding unit including said data in which an error is

10 detected and controlling the ratio of the adaptive excitation gain to the fixed excitation gain in such a way as to increase the ratio of the adaptive excitation gain when the mode indicated by said mode information is voiced mode and decrease the ratio of the adaptive 15 excitation gain when the mode indicated by said mode information is transient mode or unvoiced mode.

22. A computer-readable recording medium for storing a program, said program comprising:

20 a decoding step of decoding a lag parameter and a gain parameter in data containing coded transmission parameters including said lag parameter and said gain parameter; and

25 a controlling step of specifying an upper limit of the gain parameter in a normal decoding unit decoded immediately after decoding a decoding unit in which an error is detected and controlling the fixed excitation

gain so as to maintain a predetermined ratio with respect to the adaptive excitation gain within the range whose upper limit is specified.

**APPLICATION FOR UNITED STATES PATENT**  
**Declaration for Patent Application**

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name.

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on

the invention entitled: SPEECH DECODER AND CODE ERROR COMPENSATION METHOD

the specification of which

2 (file no. \_\_\_\_\_)

(check at least one)  is attached hereto

was filed on \_\_\_\_\_ as (5) U.S. Application Serial No. \_\_\_\_\_

and was amended \_\_\_\_\_

(if applicable)

was filed as PCT international application

Use this portion only if you are entering the U.S. National phase based on a PCT International Application designating the U.S.

8 Number PCT/JP00/04323  
 9 on 30/June/2000

and was amended under PCT Article(s) 19 and/or 34

10 on \_\_\_\_\_ (if applicable).

11 priority date claimed in PCT International Application

\*Note to Inventor: Please sign name on line 15 exactly as it appears in line 14 and insert the actual date of signing on line 16. If there are more than four inventors, please add a copy of this page for identification and signatures for the additional inventors.  
© 1998 STEVENS, DAVIS, MILLER & MOSHER, L.L.P.

## INSTRUCTIONS FOR COMPLETION OF THIS FORM

line 1 Insert the same title as is used on the specification and in the assignment.

line 2 Is optional but is provided so that you can use it to identify more readily an application prior to the time that the Patent Office application serial number is assigned. We suggest that the specification, drawings and declaration always bear a file number since it can help to get the papers together in case they become inadvertently separated. In instances where the specification is filed without a signed declaration form (under 37 CFR §1.53) a file number on a later-received separate form will assist us in associating it with the correct case.

line 3 Check this box if the specification, claims and drawing (if any) are attached to this declaration form, e.g., when filing a new patent application.

lines 4-5 Are only used in an instance where the application is already on file and the declaration from is being separately filed, e.g., when the application was originally filed without a signed declaration or where the Patent Office has required a new declaration because of a deficiency in the original declaration. In such an instance the Patent Office will require that lines 4 and 5 be completed with the filing date and application serial number already assigned.

line 6 Is used in conjunction with line 5 but only when there have been one or more amendments to the specification or claims. Line 6 is also used when the Examiner requires a new declaration because claims inserted by amendment cover subject matter not originally claimed (37 CFR §1.67).

lines 7-11 Are for PCT (Patent Cooperation Treaty) cases and are used only when you are entering the U.S. National phase (Chapter I or II) based upon a previously filed PCT International application designating the U.S.

line 7 Check this box if this is a PCT National Phase application.

line 8 Insert PCT International application number.

line 9 Insert date of filing of PCT International application.

lines 10-11 Insert the date of all amendments filed in the PCT International application. Such amendments are optional, so this line at times will not be used.

line 12a Is used in the following instances:

- (i) If a single priority is being claimed from a foreign application you need to list only the first-filed application; you do not need to list other countries if all applications were filed within one year of the U.S. filing.
- (ii) If multiple priorities are being claimed, from a plurality of applications filed in one or more countries, you must list the first filed application for each aspect of the invention. Example: if aspect A of the invention was disclosed in an application filed 11 months earlier in country X and aspect B was disclosed 9 months earlier in an application filed in country Y, then the applications in both countries X and Y must be identified. Only the first application for each aspect of the invention needs to be identified provided all applications on that aspect were filed within one year prior to the U.S. filing.
- (iii) If a non-priority application is being filed you must list all applications in all countries where corresponding foreign applications were filed more than one year prior to the U.S. filing. This is so the Examiner can check to see if any of those applications were published or patented early enough to be prior art against the U.S. application.
- (iv) If there are more than two applications to be listed we suggest that you type in on this form only "See attached Schedule A" and then list all of the previous applications on an attached sheet.

line 12b Is used to claim priority under 35 USC §119(e) based on a provisional application filed within one year of the filing of the instant application. More than one provisional application may be identified provided neither was filed more than one year earlier.

line 13 This block is used only in instances where there is a previously filed U.S. non-provisional application which was copending at the time the present application was (or is being) filed. That previous application could be a U.S. non-provisional application or the National Phase of a PCT allocation. In such a case the present application may be entitled to the priority of the previous application's U.S. filing date (and consequently the foreign priority thereof) provided the present application is identified as a continuing application (continuation, divisional or continuation-in-part) of the earlier (parent) application. If the foregoing is applicable, please fill in one line for each such prior application.

line 14 Type the inventor's proper legal name in the order specified, e.g., "John B. JONES" or "J. Bob JONES" if the inventor so prefers. It is not acceptable to use only initials such as "J. B. JONES."

line 15 The inventor's "signature" may be his (or her) usual manner of signing but it is preferable that the inventor simply write his (or her) name in his (or her) own cursive handwriting in the same order as on line 14, e.g., given name, middle initial and Family name.

line 16 Insert the actual date of signature.

line 17 Insert simply the city and state or country, e.g., "Paris, France", of the inventor's residence, not citizenship. No street address or postal code is required on this line.

line 18 Insert the inventor's citizenship. The statement of citizenship (or subject of) is a statutory requirement (35 USC §115). Simply the name of the country of citizenship, e.g., "Japan" is sufficient.

line 19 Insert the inventor's mailing address. The purpose of requiring the post office address is to enable the Patent Office to communicate directly with the inventor if desired, such as in the case of death of the U.S. attorney. It should be the address where the inventor customarily receives his (or her) mail and should include the postal code. If applicable it can be the inventor's business address or address at place of employment.

Applicants are reminded that the U.S. Patent and Trademark Office has very strict requirements as to proper execution of an application. The applicant should make sure that he reviews the declaration, prior to signing to make sure the declaration properly identifies the application and all relevant information; and should review the specification and claims (including drawings, if any) before signing the declaration. Failure to do so will require the filing of a supplemental declaration — 37 CFR §1.67(c).

Any handwritten changes to the specification, claims or drawings must be in ink personally by all of the inventors prior to signing the declaration and the adjacent left margin must be initialed and dated by all of the inventors, e.g., "JBJ 6-9-91".

Please let us know if there are any questions regarding proper completion of this form. Thank you.

An assignment, a separate document requiring separate signature and dating may be enclosed. Please look for it and sign and date it in the same manner as in lines 15 and 16 above.
